

## **Title**

rdwinselect — Window selection procedure for RD designs under local
 randomization.

#### Syntax

rdwinselect runvar [covariates] [if] [in] [, cutoff(#) obsmin(#) wmin(# #) wobs(#)
 wstep(#) wasymmetric wmasspoints nwindows(#) dropmissing statistic(stat\_name)
 p(#) evalat(point) kernel(kerneltype) approximate level(#) reps(#) seed(#)
 plot graph\_options(graphopts) genvars obsstep(#) ]

# Description

- rdwinselect implements window selection procedure based balance tests for
   regression discontinuity (RD) designs under local randomization. Specifically,
   it constructs a sequence of nested windows around the RD cutoff and reports
   binomial tests for running variable runvar and covariate balance tests for
   covariates covariates (if specified). The recommended window is the largest
   window around the cutoff such that the minimum p-values of the balance tests
   is larger than a pre-specified level for all nested (smaller) windows. By
   default, the p-values are calculated employing randomization inference
   methods. See Cattaneo, Frandsen and Titiunik (2015) and Cattaneo, Titiunik and
   Vazquez-Bare (2017) for an introduction to this methodology.
- A detailed introduction to this command is given in <u>Cattaneo</u>, <u>Titiunik and Vazquez-Bare (2016)</u>.

  Companion R functions are also available <u>here</u>.
- Companion functions are rdrandinf, rdsensitivity and rdrbounds.
- Related Stata and R packages useful for inference in RD designs are described in the following website:

https://rdpackages.github.io/

# Options |

cutoff(#) specifies the RD cutoff for the running variable runvar. Default is cutoff(0).

Window selection

- obsmin(#) specifies the minimum number of observations above and below the cutoff
  in the smallest window. Default is obsmin(10).
- wmin(# #) specifies the initial window to be used (if obsmin(#) is not specified).
   Can be a single number to specify the length of the (symmetric) initial
   window, or two numbers to specify the left and right limits of the initial
   window. Specifying both wmin(#) and obsmin(#) returns an error.
- wobs(#) specifies the number of observations to be added at each side of the cutoff at each step. Default is wobs(5).
- wstep(#) specifies the increment in window length. Specifying both wobs(#) and
   wstep(#) returns an error.
- wasymmetric allows for asymmetric windows around the cutoff (when wobs(#) is specified).
- wmasspoints specifies that the running variable is discrete and each masspoint should be used as a window.
- nwindows(#) specifies the number of windows to be used. Default is nwindows(10).
- dropmissing drop rows with missing values in covariates when calculating windows.

Statistic

statistic(stat\_name) specifies the statistic to be used. Options are:

diffmeans for difference in means statistic. This is the default option.

ksmirnov for Kolmogorov-Smirnov statistic.

ranksum for Wilcoxon-Mann-Whitney studentized statistic.

hotelling for Hotelling's T-squared statistic.

The option **ttest** is equivalent to **diffmeans** and included for backward compatibility.

- p(#) specifies the order of the polynomial for outcome adjustment model. Default is p(0).
- evalat(point) specifies the point at which the adjusted variable is evaluated.
  Allowed options are cutoff and means. Default is evalat(cutoff).
- kernel(kerneltype) specifies the type of kernel to use as weighting scheme.
   Allowed kernel types are uniform (uniform kernel), triangular (triangular
   kernel) and epan (Epanechnikov kernel). Default is kernel(uniform).

Inference

- approximate specifies that covariate balance tests should use a large-sample
   approximation instead of finite-sample exact randomization inference methods.
- level(#) specifies the minimum accepted value of the p-value from the covariate
   balance tests to be used. Default is level(.15).
- reps(#) specifies the number of replications to be used. Default is reps(1000).
- seed(#) sets the seed for the randomization test. With this option, the user can
  manually set the desired seed, or can enter the value -1 to use the system
  seed. Default is seed(666).

Generate plots and variables

- plot draws a scatter plot of the minimum p-value from the covariate balance test
   against window length implemented by the command.
- graph\_options(graphopts) graph options for plot generated by the command.
- genvars generates a variable indicating the window number corresponding to each
   observation and a variable indicating the corresponding window length.

Backward compatibility

obsstep(#) specifies the minimum number of observations to be added on each side
 of the cutoff. This option is deprecated and only included for backward
 compatibility. We recommend the use of wstep or wobs instead.

## Example: Cattaneo, Frandsen and Titiunik (2015) Incumbency Data

Setup

. use rdlocrand\_senate.dta

Window selection with three covariates and default options

. rdwinselect demmv dopen population demvoteshlag1  $\,$ 

Window selection using Kolmogorov-Smirnov statistic

. rdwinselect demmy dopen population demvoteshlaq1, stat(ksmirnov)

- Window selection with smallest window including at least 10 observations in each group and adding 3 observations in each step
  - . rdwinselect demmv dopen population demvoteshlag1, obsmin(10) wobs(3)
- Window selection setting smallest window at .5 and with .125 length increments . rdwinselect demmv dopen population demvoteshlag1, wmin(.5) wstep(.125)
- Window selection with asymptotic p-values using 40 windows with scatter plot . rdwinselect demmv dopen population demvoteshlag1, nwindows(40) approximate plot
- Modify graph options: add title and x-axis label
  - . rdwinselect demmy dopen population demvoteshlag1, nwindows(40) approx plot graph options(title(Main title) xtitle(x-axis title))

#### Saved results

rdwinselect saves the following in r():

```
Scalars
  r(minp)
                        minimum p-value from covariate test
  r(N)
                        sample size in recommended window
  r(N_left)
                        sample size in recommended window to the left of the
                         cutoff
  r(N_right)
                       sample size in recommended window to the right of the
                         cutoff
                    cutoff
left end of recommended window
right end of recommended window
when specified, increment (in observations) in each
  r(w_left)
  r(w_right)
  r(wobs)
                         window
                      initial window
  r(wmin)
  r(wstep)
                      when specified, increment (in window length) in each
                         window
  r(nwindows)
                      total number of windows evaluated
Locals
  r(seed)
                       seed used in permutations
Matrices
  r(wlist)
                       matrix with window lenghts
                        stores the minimum p-value from covariate balance test,
  r(results)
                         p-value from binomial test, sample sizes and window
                         length in each window
```
